e-mail: srl@soundresearch.co.uk

This report shall not be reproduced, except in full, without written approval of the laboratory

## 1.0 Summary

Tests have been done in SRL's Laboratory at Holbrook House, Sudbury, Suffolk, to determine the sound reduction index of a timber floor construction in accordance with BS EN ISO 140-3:1995, BS 2750:Part 3:1995

From these measurements the required results have been derived and are presented in both tabular and graphic form in Data Sheets 1 to 4.

The results are given in 1/3rd octave bands over the frequency range 50Hz to 10kHz, which is beyond that required by the test standard. Measurements outside the standard frequency range are not UKAS accredited.

**Allen Smalls**  
Laboratory Manager  
Quality Manager

**Mike Langley**  
Technical Director  
Technical Manager

Sound Research Laboratories Ltd

## **Contents**

**1.0** Summary

**2.0** Details of Measurements

**3.0** Description of Test

**4.0** Results

**Data Sheets 1 to 4**

**Drawings 1 to 4**

**Appendix 1: Test Procedure**

**Appendix 2: Measurement Uncertainty**

## 2.0 Details of Measurements

### 2.1 Location

Sound Research Laboratories Ltd  
 Holbrook House  
 Little Waldingfield  
 Sudbury  
 Suffolk  
 CO10 0TH

### 2.2 Test Dates

13 August 2004

### 2.3 Instrumentation and Apparatus Used

Make	Description	Type
E D I	Microphone Multiplexer Microphone Power Supply Unit	
Norwegian Electronics	Real Time Analyser Rotating Microphone Boom	830 231
Olivetti	Computer	M290S
Brüel & Kjaer	12mm Condenser Microphones Windshields Pre Amplifiers Microphone Calibrator Omnipower Sound Source	4166 UA0237 2639 4231 4296
Larson Davis	12mm Condenser Microphone	2560
SRL	Power Amplifiers	
Celestion	Loudspeakers	100w

Douglas Curtis	Rotating Microphone Boom	
Brannan	Hygrometer	
TOA	Graphic Equalizer Power Amplifier	E-1231 DPA-800

## 2.4 References

BS EN ISO 140-3:1995	Laboratory measurement of airborne sound insulation of building elements
BS EN ISO 717-1:1997	Rating of sound insulation in buildings and of building elements. Airborne Sound Insulation.

## 2.5 Personnel Present

Paul Baron	Gang Nail Systems
------------	-------------------

## **3.0 Description of Test**

### **3.1 Description of Sample**

Timber floor system consisting of:

22mm tongue and grooved chipboard (15.7kg/m<sup>2</sup>) screwed to Gang Nail Systems A1 engineered joists.

Joists at 600mm centres, resting in test aperture.

Chipboard sealed at perimeter with mastic.

Ceiling of 15mm British Gypsum SoundBloc (12.8kg/m<sup>2</sup>) screwed to joists.

Chipboard and plasterboard weighed by SRL.

See also Diagrams 1 to 4 (supplied by Gang Nail Systems).

Please note detail on drawings describes chipboard being nailed, where it was actually screwed.

Four tests were done, details in section 4 and on data sheets in this report.

Sampling plan: none (only enough material for test)

Sample condition: new

Details supplied by Gang Nail Systems & SRL

Sample installed by SRL

### **3.2 Sample Delivery date**

11 August 2004

### **3.3 Test Procedures**

The sample was mounted and tested in accordance with the relevant standard. The method and procedure is described in Appendix 1.

## 4.0 Results

The results of the measurements and subsequent analysis are given in Data Sheets 1 to 4 and summarised below.

Results relate only to the items tested.

<b>SRL Test No.</b>	<b>Description in Brief</b>	<b>R<sub>w</sub></b>
2	22mm chipboard screwed at 300mm centres (not glued)	40
3	As test 2, glue applied under chipboard to joists and to chipboard joints.	40
4	As test 3, half of the screws removed from chipboard.	40
5	As test 4, all screws removed from chipboard	42

### Floor System Test Method

#### Measurement of Sound Transmission in accordance with BS EN ISO 140-3:1995 - TP15

In the laboratory, airborne sound transmission is determined from the difference in sound pressure levels measured across a test sample installed between two reverberant rooms. The difference in measured sound pressure levels is corrected for the amount of absorption in the receiving room. The test is done under conditions which restrict the transmission of sound by paths other than directly through the sample. The source sound field is randomly incident on the sample.

The test sample is constructed in the floor aperture between the two rectangular reverberant (i.e. acoustically "live") rooms, both of which are constructed from 215mm thick brickwork. The floor/ceiling which forms the common area between the two rooms has overall dimensions of 4.85m x 3.9m, into which is an aperture 3.98m x 2.5m. The test sample is built and sealed carefully into the aperture.

The upper room, termed the source room, has a volume of 50m<sup>3</sup> and is isolated by the surrounding structure by the use of resilient mountings. The lower or receiving room has a volume of 115m<sup>3</sup>. Reverberation time measurements are done in the receiving room to calibrate it.

Broad band pink noise is produced in the source room from an electronic generator and power amplifier. The resulting sound pressure levels in both rooms are sampled using a microphone mounted on an oscillating boom and connected to a real time analyser. The signal is filtered into one third octave band widths, integrated and averaged. The value obtained at each frequency is known as the average sound pressure level for either the source or the receiving room. The change in level across the test sample is termed the sound pressure level difference, i.e.

$$D = L_1 - L_2$$

D is the sound pressure level difference in dB

L<sub>1</sub> is the average sound pressure level in the source room in dB

L<sub>2</sub> is the average sound pressure level in the receiving room in dB

The sound reduction index (R) is also known by the American term "sound transmission loss". It is defined as the number of decibels by which sound energy

randomly incident on the test sample, is reduced in transmitting through it and is given by the formula:

$$R = D + 10\log(S/A) \text{ in decibels}$$

where

S is the area of the sample (m<sup>2</sup>)

A is the total absorption in the receiving room (m<sup>2</sup>)

The sound reduction index is an expression of the laboratory sound transmission performance of a particular element or construction. It is a function of the mass, thickness, sealing and method of mounting, but is independent of the overall area of the sample.

However, when an example of this floor is installed on site, the sound insulation obtained will depend upon its surface area, as well as the absorption in the receiving room. The larger the area the greater the sound energy transmitted. Also, the overall sound insulation of a floor is affected by the sound transmission through other building elements, some of which may have an inferior performance to the sample. In practice, therefore, the potential sound reduction index of a sample is not fully realised on site. Furthermore, the sound reduction index of a particular sample floor can only be measured accurately in a laboratory, because only under such controlled conditions can the sound transmission path be limited to the sample under test.

R<sub>w</sub> is a single figure rating of sound insulation and is calculated in accordance with the relevant section of BS EN ISO 717-1:1997.

## Appendix 2

### Measurement Uncertainty BS EN ISO 140-3:1995 - TP15

The following values of uncertainty are based on a standard uncertainty multiplied by a coverage factor of  $k = 2$ , which provides a level of confidence of approximately 95%.

Frequency, Hz	Uncertainty, $\pm$ dB
100	2.6
125	2.4
160	2.1
200	2.1
250	1.5
315	1.5
400	1.2
500	1.2
800	1.0
1000	1.0
1250	1.0
1600	1.0
2000	1.0
2500	1.0
3150	1.0
